Metal Roofing Mfg Introduces Batten Board Metal Panels to Architectural Product Offerings

October 30, 2026

RYDAL, GA - October 30, 2026 -
Metal Roofing Mfg announces the expansion of its manufactured product line to include batten board metal panels in Cartersville, GA. The introduction of these materials establishes an updated structural option for regional construction projects. Operating since 2003, the company fabricates metal roofing and siding for various structural applications.

The fabrication facility, situated in Northwest Georgia, has manufactured exterior materials for more than two decades. The structural design of these exterior panels features raised seams and a structured physical appearance. This specific profile establishes a vertical line layout applied to exterior walls or roofing frameworks. The facility utilizes patented in-house manufacturing equipment to produce these units. Alongside the panel manufacturing process, the business employs a patented mechanical device engineered specifically for installing batten boards, which ensures standardized application across various building surfaces.

Metal exterior products require specific material properties to function in diverse weather conditions. Metal Roofing Mfg constructs its panels using recycled materials, which are fully recyclable at the conclusion of their structural lifespan. This composition aligns with standard sustainable building practices by minimizing physical waste. The metal construction inherently delivers fire resistance, adding a standardized layer of property protection required by modern building codes. Additionally, the physical surface of the metal reflects solar radiation. This reflective property minimizes heat absorption within the building envelope, a mechanical function that impacts overall internal temperature regulation.

The manufacturing line produces multiple styles of metal coverage, including English and Tuff-Rib configurations. Production capabilities at the facility allow for the fabrication of materials in over twenty different exterior colors. Applying distinct color finishes creates options for matching existing architectural blueprints. The paint systems applied to the metal surfaces carry specific warranty durations extending up to forty years, while Galvalume substrate options include standard material coverage spanning fifteen to twenty-five years. These technical specifications apply to the newly introduced panels as well as standard

roofing sheets, pole barn kits, and carport structures produced at the manufacturing center.

In addition to exterior panels, Metal Roofing Mfg fabricates custom pole barn kits. These kits bundle the necessary structural components into a single package for standardized assembly. The production facility maintains inventory and processing systems that allow material orders to be completed for facility pickup in as little as one hour. This operational timeline facilitates continuous workflow for builders sourcing local materials. The carport structures are similarly manufactured to withstand regional weather variables while utilizing the same metal roofing color options available for standard building applications.

The introduction of new exterior cladding options reflects broader shifts in construction material sourcing. Modern building projects frequently require components that integrate functional longevity with standardized installation methods. The panel units address these physical requirements by combining a rigid structural format with established weather-resistance properties. The raised seams of the physical profile prevent water pooling and direct precipitation away from critical structural joints. This mechanical design decreases the probability of moisture penetration and subsequent degradation of the underlying building framework.

Fabricating these materials locally reduces the logistical variables associated with long-distance material transport. The centralized production establishes a direct supply chain for construction projects. The localized manufacturing model ensures that the physical dimensions and structural tolerances of the metal panels are maintained from the fabrication floor to the construction site. By standardizing the production process through patented in-house technology, the company maintains consistent dimensional accuracy across all fabricated metal units. Operating a localized supply chain also mitigates common delays tied to interstate shipping, allowing regional construction schedules to proceed without interruption.

The physical characteristics of metal panels, specifically their resistance to rot, insect damage, and impact, present an alternative to traditional wood or composite siding materials. The style mimics the vertical lines of historical wood construction while utilizing the structural rigidity of modern metal alloys. This physical composition removes the need for frequent sealing or board replacement typically associated with organic exterior materials. This long-term structural stability remains a primary factor in modern building specifications. Metal Roofing Mfg operates as a family-owned manufacturing business, maintaining regular production hours throughout the workweek. By concentrating specifically on metal materials, the facility maintains specialized production lines rather than a generalized inventory. This singular operational focus allows the manufacturing center to process large material requests efficiently.

The facility?s ongoing production updates aim to ensure a consistent supply of structural materials for the region. The operational expansion into specific cladding formats represents a continuation of the business?s

fabrication capabilities. For builders and property developers, the availability of locally produced batten board metal panels in Cartersville, GA, establishes a direct source for exterior components.
