

Silicon Valley Pest Control Agrees with Rodent Control Research

May 08, 2019

May 08, 2019 - PRESSADVANTAGE -

Groundbreaking new rodent control research funded by the National Pest Management Association (NPMA) dispelled some long-thought myths about cats as an effective means of rodent control. It turns out that cats do not successfully kill and control rat populations. Although cats' stalking activity may initially keep rats out of sight, the rodents will patiently wait them out and return undeterred once the cats lose interest and leave the scene. Scientists studied individual rat behavior using scent detection and RFID-technology, better known as micro-chipping, to learn more about individual rat behavior.

The researchers also monitored how often a rat frequented remote sensors and found certain odors to be more attractive than others in luring rodents to a trap or feeding station. Historically, rats have always been extremely problematic in society as both carriers of disease and threats to our property and food. Despite the risks they present, rats are also one of the most under-researched animals because they are so uniquely adept at living in close contact with humans but remaining just out of sight. This research was conducted to learn more about individual rat behavior and to seek information to inform better rodent control methods for the professional pest control industry.

One study revealed when exploring scent detection male scents alone cause both female and male rats to investigate, but then ultimately avoid an area in the future. Mixed male and female pheromones cause rats to respond more favorably to the scent compared to male-only scents. Female-only pheromones are most attractive to both male and female rats and elicit the strongest response.

When it came to cats and rodent control, feral cats were observed over the course of a five-month period and their presence was recorded more than 300 times by the cameras monitoring the research site and active rat colonies located nearby. In that timeframe, less than one percent of the cat and rat encounters resulted in a rat being killed; despite, stalking behavior being observed 20 times. Rats are less likely to be seen on the day-of or the day after cats are present. For every cat sighting observed, rats were nearly 20 percent more likely to move toward a shelter. Although rats were less likely to be seen, the feral cats had no observable long-term impact on the rat population. The rats went into hiding but came back later, determining that cats are not an effective measure in rat control in urban settings.
