SafeAir Certified Mold Inspection Inc Releases New Air Quality Testing Resource

July 16, 2026

July 16, 2026 -

SafeAir Certified Mold Inspection Inc has published a new educational resource titled "Air Quality Testing" that explains how professional air quality testing can help identify mold concerns and provide detailed information about indoor air conditions. The new guidance is available on the company's website and outlines how air sampling is used as part of a mold inspection when mold growth is suspected. The resource was developed to help homeowners, property managers, real estate professionals, and business owners better understand the purpose of air quality testing and the information it can provide during a mold investigation.

The new resource explains the role of air quality testing in evaluating indoor environments where mold may be present but not immediately visible. It describes the testing process, the types of laboratory information that can be collected, and how indoor and outdoor air samples are compared to help determine whether mold levels inside a building differ from normal outdoor conditions. The company notes that this comparison provides useful context because mold spores naturally exist in outdoor air, making reference samples an important part of the evaluation process.

"People often know something is not right indoors but may not know what information professional testing can provide," said Alex Laldin, Marketing Director for SafeAir Certified Mold Inspection Inc. "This new resource explains the testing process in plain language so property owners can better understand how air sampling fits into a mold inspection and how laboratory results are interpreted. The goal is to help people understand what professional testing measures and how that information can support decisions about a property."

According to the information released by SafeAir Certified Mold Inspection Inc, air sampling uses a calibrated air pump to collect a measured volume of air onto a collection device. The collected material is then examined under a microscope to identify mold species and estimate the number of airborne spores present in the sampled environment. The company states that indoor samples are evaluated alongside outdoor reference samples because similar mold types and spore counts indoors and outdoors may indicate that an indoor mold problem is less likely.

The educational resource also explains that laboratory reports can include the types of mold detected, raw mold spore counts, estimated mold spore concentrations, and total airborne mold measurements. In addition to identifying mold spores, microscopic examination may also identify other airborne particles that could affect indoor air quality. The company explains that these findings provide documented information that can be reviewed together with observations made during the inspection process.

The published guidance notes that air quality testing is generally performed after a visual inspection when conditions suggest possible mold growth or when further information is needed about indoor air conditions. Visible staining, moisture problems, water damage, or reports of musty odors may lead an inspector to recommend air sampling as part of a broader evaluation. The company explains that inspection findings and laboratory results are intended to complement one another rather than replace a physical assessment of the property.

The resource also describes situations in which air quality testing may help document indoor conditions before remediation work begins or provide additional information after mold concerns have been identified. By explaining how sampling methods work and what laboratory reports contain, the company aims to give homeowners, property managers, and business owners a clearer understanding of the information available through professional testing. The guidance also explains that laboratory analysis provides objective data that can be reviewed as part of the overall inspection process.

SafeAir Certified Mold Inspection Inc states that its inspection process focuses on gathering information that can be evaluated alongside findings from the physical inspection. The educational resource emphasizes that air quality testing is intended to provide measurable information about airborne mold spores and related particles rather than relying on visual observations alone. The company notes that the testing process is one

part of a complete mold inspection and is used to provide additional information when conditions warrant further evaluation.

The publication of this educational resource reflects the company's ongoing effort to provide factual information about mold inspections and indoor air quality through its website. By explaining common inspection methods and laboratory testing procedures in clear language, the company seeks to help readers better understand how professional mold evaluations are performed and what information testing can provide when indoor mold concerns arise.

SafeAir Certified Mold Inspection Inc provides mold inspection, mold testing, air quality testing, consultation, and analysis for residential and commercial properties. According to information published on its website, the company serves clients throughout Georgia and North Carolina and offers inspection services for individuals who suspect mold or want to evaluate indoor air quality. Additional educational information about mold inspection and indoor environmental testing is available through the company's online resource library.
